Swift
Racket

## Dart

## THE DAWN OF MAAN

Functions

## An Example

- What if we wanted to add up all the numbers from a to b?
(define (sum ab)
(if (> ab)

0
(+ a
(sum (+ a 1) b))))

## An Example

- What if we wanted to add up all the squares numbers from a to $b$ ?
(define (sum a b)
(if (> a b)

0
(+ (expt a 2)
(sum (+ a 1) b))))

## An Example

- What if we wanted to add up all the absolute values of the numbers from a to $b$ ?
(define (sum ab)
(if (> ab)

0
(+ (abs a)
(sum (+ a 1) b))))

## These functions are all very similar

- All three of these functions differ only in how the sequence of integers from $a$ to $b$ are transformed before they are all added together.
- The adding process itself is identical in all of the functions:
(define (sum-something a b)
(if (> a b)
0
(+ (do something to a)
(sum-something (+ a 1) b))))
- What if there were a general sum function that could sum up any sequence of this form?

## A function that takes a function

- Imagine a function that could take another function as an argument:
(define (sum-any func $a \mathrm{~b}$ )
(if (> a b)
0
(+ (func a)
(sum-any func (+ a 1) b))))

## Sum-any in action!

(sum-any sqrt 1 10)
$=>$ sqrt(1) + sqrt(2) + sqrt(3) + ...
=> about 22.5
(define (square $x$ ) (* $x$ x))
(sum-any square 1 4)
$=>1^{\wedge} 2+2^{\wedge} 2+3^{\wedge} 2+4^{\wedge} 2=>1+4+9+$
$16=>30$
(define (identity $x$ ) $x$ )
(sum-any identity 1 4)
$\Rightarrow 10$

## How to use sum-any

- You can put the name of any function in place of sqrt, square, or identity, and sum-any will compute
$f(a)+f(a+1)+f(a+2)+\ldots+f(b)$
- Provided $\mathbf{f}$ is a function of a single numeric argument.
- What if you want to compute $f\left(a^{\wedge} 2 / 2\right)+f\left((a+1)^{\wedge} 2 / 2\right)+\ldots$
- Fine to do:
(define (silly-function x) (/ (* x x) 2))
(sum-any silly-function 1 10)
- Wouldn't it be nicer if we didn't have to name that silly function?

## Anonymous Functions

- Functional programming languages allow us to create functions without names.
- In Racket, we use the keyword lambda for this:
(lambda (arg1 arg2...) body)
- This expression represents an anonymous function.
- Kind of like a "function literals."

## Aside: lambda calculus

- Formal system for computation based on function abstraction and application.
- Church-Turing thesis (193637) proved lambda calculus is equivalent in power to
Turing machines.

Alonzo Church

## Anonymous Functions

- Use an anonymous function when you need a "temporary" function:
(sum-any (lambda (x) (/ (* x x) 2)) 1 10) is better style than
(define (silly-function x) (/ (* x x) 2))
(sum-any silly-function 1 10)
- Compare:
(sum-any (lambda (x) (* x x)) 1 10) and
(define (square (x) (* x x)) (sum-any square 1 10)

## Using anonymous functions

- Most common use: Argument to a higher-order function
- Don't need a name just to pass a function
(define (triple x) (* 3 x); named version
(lambda (x) (* 3 x)) ; anonymous version
- But: Cannot use an anonymous function for a recursive function
- Because there is no name for making recursive calls

## Named functions vs anonymous functions

- Named functions are mostly indistinguishable from anonymous functions.
- In fact, naming a function with define uses the anonymous form behind the scenes:
(define (func arg1 arg2 ...) expression)
is converted to:
(define func (lambda (arg1 arg2 ...) expression))
- It is poor style to define unnecessary functions in the global (toplevel) environment
- Use either nested defines, or anonymous functions.

## Higher-order functions

- A higher-order function is a function that either takes a function (or more than one function) as an argument, or returns a function as a return value.
- Possible because functions are first-class values (or first-class citizens), meaning we can use a function wherever we use a value.
- First class citizens can be arguments to functions, returned from functions, bound to variables, and stored in data structures.
- In Racket, a function can be stored anywhere any other data type would be stored.
- Most common use is as an argument / result of another function

## Higher-order functions

- Let's see another:
(define (do-n-times func $n \mathrm{x}$ )
(if (= n 0) $x$
(do-n-times func (-n 1) (func $x)$ )))
- This function computes $f(f(f . . .(x)))$, where the number of applications of $f$ is $n$.

## Some uses for do-n-times

- Get-nth:

```
- (define (get-nth lst n)
    (car (do-n-times cdr n lst)))
```

- Exponentiation:

```
- (define (power x y) ; raise x to the y power
    (do-n-times (lambda (a) (* x a)) y 1))
```

- Note how in the exponentiation example, the anonymous function uses variable $x$ from the outer environment.
- Couldn't do that without being able to nest functions.
- Note how do-n-times can work with any data type (e.g., lists, numbers...)

## A style point

Compare:
(if x \#t \#f)

With:

> (lambda (x) (f x)

So don't do this:

```
    (do-n-times (lambda (x) (cdr x)) 3 '(2 4 6 8))
```

When you can do this:

$$
\text { (do-n-times cdr } 3^{\prime}\left(\begin{array}{llll}
2 & 4 & 6 & 8
\end{array}\right)
$$

## What does this function do?

(define (mystery lst)
(if (null? lst) '()
(cons (car lst) (mystery (cdr lst)))))

## Map

(define (map func lst)
(if (null? lst) '() (cons (func (car lst)) (map func (cdr lst)))))

Map is, without doubt, in the higher-order function hall-of-fame

- The name is standard (same in most languages)
- You use it all the time once you know it: saves a little space, but more importantly, communicates what you are doing
- Built into Racket, so you don't have to include this definition in programs that use map.

## Filter

```
(define (filter func lst)
    (cond ((null? lst) '())
    ((func (car lst))
    (cons (car lst) (filter func (cdr lst))))
    (#t
    (filter func (cdr lst)))))
```

Filter is also in the hall-of-fame

- So use it whenever your computation is a filter
