ADT = abstract data type

Interface

vs

implementation

WHAT something does

how something is done

→ 2 components

- ↳ Short description of what the data type represents (abstractly)
- ↳ List of operations that the data type is capable of. These operations don't give low-level details about how they work. They just specify WHAT operations the data type can do.

Ex : Cars

Interface

- steering wheel
- gas pedal
- brake ~~pedal~~

implementation

- ? car?
- engine?
- activate brakes

} different for
gas vs
elec cars

ADT = interface

In order to actually write a program, ADTs must be paired w/ an implementation.

"Data Structure" → the implementation part that is paired w/ the ADT
→ implementation + interface

LIST ADT

→ description: A list consists of a collection of positions, each of which contains a single element of the list. Each position has a unique index, which is an integer in the range from $0 \dots n-1$, where $n = \#$ of elements in the list.
This description says nothing about how the list is stored in memory.

Operations

- get the length/size of the list
- add things into our list
- remove things from our list
- retrieve an item of the list at a specific index (GET)
- sort the list
- modify (change an element @ a given index) (SET)
- merge 2 lists together
- create a new (blank) list

How to implement this RList interface?

What is a data structure we could use to implement RList?

→ Java arrays

Big diff b/w Java arrays vs ArrayLists

int array[10];

FIXED

SIZE

ArrayList<Integer> list =
new ArrayList<>();

GROW +
SHRINK

NOTE:

Programmers need to know for each function how much memory the function will need (total size of all vars)

Java `int x;` → 4 bytes
`long y;` → 8 bytes
`int array[10];` → $4 \text{ bytes} \times 10 = 40 \text{ bytes}$

User's perspective (interface)

| | | |
|----|----|----|
| 0 | 1 | 2 |
| 10 | 20 | 30 |

↓ append(40)

| | | | |
|----|----|----|----|
| 0 | 1 | 2 | 3 |
| 10 | 20 | 30 | 40 |

↓ append(50)

| | | | | |
|----|----|----|----|----|
| 0 | 1 | 2 | 3 | 4 |
| 10 | 20 | 30 | 40 | 50 |

↓ append(60)

| | | | | | |
|----|----|----|----|----|----|
| 10 | 20 | 30 | 40 | 50 | 60 |
|----|----|----|----|----|----|

Programmer's perspective (implementation)

| | | | | |
|----|----|----|---|---|
| 0 | 1 | 2 | 3 | 4 |
| 10 | 20 | 30 | ? | ? |

capacity
size = 3 extra array slots

| | | | | |
|----|----|----|----|---|
| 0 | 1 | 2 | 3 | 4 |
| 10 | 20 | 30 | 40 | ? |

| | | | | |
|----|----|----|----|----|
| 0 | 1 | 2 | 3 | 4 |
| 10 | 20 | 30 | 40 | 50 |

out of space 😕

"expand" the array

- create a new array w/ extra spots
- copy the old array into the new array

new array

| | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| 10 | 20 | 30 | 40 | 50 | 60 | ? | ? | ? | ? |

| | | | | | |
|-----------|----|----|----|----|----|
| old array | 9 | 9 | 9 | 9 | 9 |
| 10 | 20 | 30 | 40 | 50 | 60 |

Our Implementation : class RArrayList

int[] data; → hold the elements of the list
int size → can't grow!
→ size from the user's perspective

How do we detect when we are out of space?

size vs data.length
" == " → out of space
